University of Delaware, Newark, DE 19716, USA*

A gauged $U(1)_{B-L}$ symmetry predicts three right handed neutrinos and its spontaneous breaking automatically yields the seesaw mechanism. In a supersymmetric setting this breaking can be nicely linked with inflation to yield $\delta T/T$ proportional to $(M_{B-L}/M_P)^2$, where M_{B-L} (M_P) denote the $B-L$ breaking (Planck) scale. Thus M_{B-L} is estimated to be of order 10^{16} GeV, and the heaviest right handed neutrino mass is less than or of order 10^{14} GeV. A second right handed neutrino turns out to have a mass of order $10 - 10^2 T_r$, where T_r ($\lesssim 10^9$ GeV) denotes the reheat temperature. A $U(1)_R$ symmetry plays an essential role in implementing inflation and leptogenesis, resolving the MSSM μ problem and eliminating dimension five nucleon decay. An unbroken Z_2 subgroup plays the role of matter parity. The scalar spectral index $n_s = 0.99 \pm 0.01$ for the simplest models, while in smooth hybrid inflation $n_s \geq 0.97$. The tensor to scalar ratio r is negligible, and $dn_s/d \ln k \lesssim 10^{-3}$.

I. INTRODUCTION

Physics beyond the Standard Model (SM) is required by the following experimental observations:

- Neutrino Oscillations: $\Delta m_{\text{SM}}^2 \lesssim 10^{-10} \text{ eV}^2 \ll (\text{mass difference})^2$ needed to understand atmospheric and solar neutrino observations;
- CMB Anisotropy ($\delta T/T$): requires inflation which cannot be realized in the SM;
- Non-Baryonic Dark Matter ($\Omega_{\text{CDM}} = 0.25$): SM has no plausible candidate;
- Baryon Asymmetry ($n_b/s \sim 10^{-10}$): Not possible to achieve in the SM.

Recall that at the renormalizable level the SM possesses a global $U(1)_{B-L}$ symmetry. If the symmetry is gauged, the anomaly cancellation requires the existence of three right handed neutrinos. An important question therefore is the symmetry breaking scale of $U(1)_{B-L}$. Note that this scale is not fixed by the evolution of the three SM gauge couplings. Remarkably, we will be able to determine the M_{B-L} by implementing inflation. With M_{B-L} well below the Planck scale the seesaw mechanism enables us to realize light neutrino masses in the desired range. Furthermore, it will turn out that leptogenesis is a natural outcome after inflation is over.

The introduction of a gauge $U(1)_{B-L}$ symmetry broken at a scale well below the Planck scale exacerbates the well known gauge hierarchy problem. There are at least four potential hierarchy problems one could consider:

- $M_W \ll M_P$;
- $M_{B-L} \ll M_P$ (required by neutrino oscillations);
- $m_\chi \ll M_P$ (where m_χ denotes the inflaton mass);
- $f_a \sim 10^{10} - 10^{12}$ GeV ($\ll M_P$), where f_a denotes the axion decay constant.

Supersymmetry (SUSY) can certainly help here, especially if the SUSY breaking scale in the observable sector is of order TeV. Thus, it seems that a good starting point, instead of $\text{SM} \times U(1)_{B-L}$, could be $\text{MSSM} \times U(1)_{B-L}$. The Z_2 ‘matter’ parity associated with the MSSM has two important consequences. It eliminates rapid (dimension four) proton decay, and it delivers a respectable cold dark matter candidate in the form of LSP. However, Planck scale suppressed dimension five proton decay is still present and one simple solution is to embed Z_2 in a $U(1)_R$ symmetry. It turns out that the R symmetry also plays an essential role in realizing a compelling inflationary scenario and in the resolution of the MSSM μ problem. Finally it seems natural to extend the above discussion to larger groups, especially to $SO(10)$ and its various subgroups.

II. SUPERSYMMETRIC HYBRID INFLATION MODELS

In this section, we review a class of supersymmetric hybrid inflation models [1, 2, 3] where inflation can be linked to the breaking of $U(1)_{B-L}$. We compute the allowed range of the dimensionless coupling in the superpotential and the dependence of the spectral index on

this coupling, in the presence of canonical supergravity (SUGRA) corrections.

The simplest supersymmetric hybrid inflation model [4] is realized by the renormalizable superpotential [5]

$$W_1 = \kappa S(\Phi\bar{\Phi} - M^2) \quad (1)$$

where $\Phi(\bar{\Phi})$ denote a conjugate pair of superfields transforming as nontrivial representations of some gauge group G , S is a gauge singlet superfield, and $\kappa (> 0)$ is a dimensionless coupling. A suitable $U(1)$ R-symmetry, under which W_1 and S transform the same way, ensures the uniqueness of this superpotential at the renormalizable level [4]. In the absence of supersymmetry breaking, the potential energy minimum corresponds to non-zero vacuum expectation values (VEVs) ($= M$) in the scalar right handed neutrino components $|\langle \nu_H^c \rangle| = |\langle \bar{\nu}_H^c \rangle|$ for Φ and $\bar{\Phi}$, while the VEV of S is zero. (We use the same notation for superfields and their scalar components.) Thus, G is broken to some subgroup H which, in many interesting models, coincides with the MSSM gauge group.

In order to realize inflation, the scalar fields $\Phi, \bar{\Phi}, S$ must be displaced from their present minima. For $|S| > M$, the $\Phi, \bar{\Phi}$ VEVs both vanish so that the gauge symmetry is restored, and the tree level potential energy density $\kappa^2 M^4$ dominates the universe, as in the originally proposed hybrid inflation scenario [5, 6, 7]. With supersymmetry thus broken, there are radiative corrections from the $\Phi - \bar{\Phi}$ supermultiplets that provide logarithmic corrections to the potential which drives inflation.

In one loop approximation the inflationary effective potential is given by [4]

$$V_{\text{LOOP}} = \kappa^2 M^4 \left[1 + \frac{\kappa^2 \mathcal{N}}{32\pi^2} \left(2 \ln \frac{\kappa^2 |S|^2}{\Lambda^2} + (z+1)^2 \ln(1+z^{-1}) + (z-1)^2 \ln(1-z^{-1}) \right) \right], \quad (2)$$

where $z \equiv x^2 \equiv |S|^2/M^2$, $\mathcal{N}$ is the dimensionality of the $\Phi, \bar{\Phi}$ representations, and Λ is a renormalization mass scale.

The scalar spectral index n_s is given by [7, 8]

$$n_s \cong 1 - 6\epsilon + 2\eta, \quad \epsilon \equiv \frac{m_P^2}{2} \left(\frac{V'}{V} \right)^2, \quad \eta \equiv \frac{m_P^2 V''}{V}, \quad (3)$$

where $m_P \simeq 2.4 \times 10^{18}$ GeV is the reduced Planck mass ($M_P/\sqrt{8\pi}$). We are going to use units $m_P = 1$, although sometimes we will write m_P explicitly. The primes denote derivatives with respect to the normalized real scalar field $\sigma \equiv \sqrt{2}|S|$. For relevant values of the parameters ($\kappa \ll 1$), the slow roll conditions ($\epsilon, \eta \ll 1$) are violated only ‘infinitesimally’ close to the critical point at $x = 1$ ($|S| = M$) [3]. So inflation continues practically until this point is reached, where it abruptly ends.

The number of e -folds after the comoving scale l has

crossed the horizon is given by

$$N_l = \frac{1}{m_P^2} \int_{\sigma_f}^{\sigma_l} \frac{V d\sigma}{V'} \quad (4)$$

where σ_l is the value of the field at the comoving scale l and σ_f is the value of the field at the end of inflation. Using Eqs. (2, 4), we obtain

$$\kappa \approx \frac{2\sqrt{2}\pi}{\sqrt{\mathcal{N}N_0}} y_0 \frac{M}{m_P}. \quad (5)$$

Here, the subscript 0 implies that the values correspond to the comoving scale $l_0 = 2\pi/k_0$, with $k_0 \equiv 0.002$ Mpc $^{-1}$. $N_0 \approx 55$ is the number of e -folds¹ and

$$y_0^2 = \int_1^{x_0^2} \frac{dz}{zf(z)}, \quad y_0 \geq 0, \quad (6)$$

with

$$f(z) = (z+1) \ln(1+z^{-1}) + (z-1) \ln(1-z^{-1}). \quad (7)$$

The amplitude of the curvature perturbation $\mathcal{P}_{\mathcal{R}}^{1/2}$ is given by²

$$\mathcal{P}_{\mathcal{R}}^{1/2} = \frac{1}{2\sqrt{3}\pi m_P^3} \frac{V^{3/2}}{|V'|}. \quad (8)$$

Using Eqs. (2, 5, 8), $\mathcal{P}_{\mathcal{R}}^{1/2}$ is found to be [3, 4, 9]

$$\mathcal{P}_{\mathcal{R}}^{1/2} \approx 2 \left(\frac{N_0}{3\mathcal{N}} \right)^{1/2} \left(\frac{M}{m_P} \right)^2 x_0^{-1} y_0^{-1} f(x_0^2)^{-1}. \quad (9)$$

Up to now, we ignored supergravity (SUGRA) corrections to the potential. More often than not, SUGRA corrections tend to derail an otherwise successful inflationary scenario by giving rise to scalar (mass)² terms of order H^2 , where H denotes the Hubble constant. Remarkably, it turns out that for a canonical SUGRA potential (with minimal Kähler potential $|S|^2 + |\Phi|^2 + |\bar{\Phi}|^2$), the problematic (mass)² term cancels out for the superpotential W_1 in Eq. (1) [5]. This property also persists when non-renormalizable terms that are permitted by the $U(1)_R$ symmetry are included in the superpotential.³

¹ $N_0 \simeq 54 + (1/3) \ln(T_r/10^9 \text{ GeV}) + (2/3) \ln(v/10^{14} \text{ GeV})$, where T_r is the reheat temperature and v^4 is the false vacuum energy density.

² Note that the quadrupole CMB anisotropy $\delta T/T = \mathcal{P}_{\mathcal{R}}^{1/2}/2\sqrt{15}$.

³ In general, K is expanded as $K = |S|^2 + |\Phi|^2 + |\bar{\Phi}|^2 - \alpha |S|^4/m_P^2 + \dots$, and only the $|S|^4$ term in K generates a (mass)² for S , which would spoil inflation for $\alpha \sim 1$ [10]. From the requirement $\sigma < m_P$, one obtains an upper bound on α ($\sim 10^{-2}$ for $\kappa \gtrsim 10^{-2}$, $\sim 10^{-5}$ for $\kappa \sim 10^{-5}$) [11]. We should note that, since the superpotential is linear in the inflaton, the presence of other fields with Planck scale VEVs also induce an inflaton mass of order H . Some ways to suppress the inflaton mass are discussed in [12].

The scalar potential is given by

$$V = e^K \left[\left(\frac{\partial^2 K}{\partial z_i \partial z_j^*} \right)^{-1} D_{z_i} W D_{z_j^*} W^* - 3|W|^2 \right] + V_D, \quad (10)$$

with

$$D_{z_i} W = \frac{\partial W}{\partial z_i} + \frac{\partial K}{\partial z_i} W, \quad (11)$$

where the sum extends over all fields z_i , and $K = \sum_i |z_i|^2$ is the minimal Kähler potential. The D-term V_D vanishes in the D-flat direction $|\bar{\Phi}| = |\Phi|$. From Eq. (10), with a minimal Kähler potential one contribution to the inflationary potential is given by [5, 13, 14, 15]

$$V_{\text{SUGRA}} = \kappa^2 M^4 \left[\frac{|S|^4}{2} + \dots \right]. \quad (12)$$

There are additional contributions to the potential arising from the soft SUSY breaking terms. In $N = 1$ SUGRA these include the universal scalar masses equal to $m_{3/2}$ ($\sim \text{TeV}$), the gravitino mass. However, their effect on the inflationary scenario is negligible, as discussed below. The more important term is the A term $(2-A)m_{3/2}\kappa M^2 S(+\text{h.c.})$. For convenience, we write this as $a m_{3/2}\kappa M^2 |S|$, where $a \equiv 2|2-A|\cos(\arg S + \arg(2-A))$. The effective potential is approximately given by Eq. (2) plus the leading SUGRA correction $\kappa^2 M^4 |S|^4/2$ and the A term:

$$V_1 = \kappa^2 M^4 \left[1 + \frac{\kappa^2 \mathcal{N}}{32\pi^2} \left(2 \ln \frac{\kappa^2 |S|^2}{\Lambda^2} + (z+1)^2 \ln(1+z^{-1}) + (z-1)^2 \ln(1-z^{-1}) \right) + \frac{|S|^4}{2} \right] + a m_{3/2} \kappa M^2 |S| \quad (13)$$

We perform our numerical calculations using this potential, taking $|a m_{3/2}| = 1 \text{ TeV}$. It is, however, instructive to discuss small and large κ limits of Eq. (13). For $\kappa \gg 10^{-3}$, $1 \gg \sigma \gg \sqrt{2}M$, and Eq. (13) becomes

$$V_1 \simeq \kappa^2 M^4 \left[1 + \frac{\kappa^2 \mathcal{N}}{32\pi^2} 2 \ln \frac{\kappa^2 \sigma^2}{2\Lambda^2} + \frac{\sigma^4}{8} \right] \quad (14)$$

to a good approximation. Comparing the derivatives of the radiative and SUGRA corrections one sees that the radiative term dominates for $\sigma^2 \lesssim \kappa \sqrt{\mathcal{N}}/2\pi$. From $3H\dot{\sigma} = -V'$, $\sigma_0^2 \simeq \kappa^2 \mathcal{N} N_0/4\pi^2$ for the one-loop effective potential, so that SUGRA effects are negligible only for $\kappa \ll 2\pi/\sqrt{\mathcal{N}} N_0 \simeq 0.1/\sqrt{\mathcal{N}}$. (For $\mathcal{N} = 1$, this essentially agrees with [14]).

$\mathcal{P}_{\mathcal{R}}^{1/2}$ is found from Eq. (14) to be

$$\mathcal{P}_{\mathcal{R}}^{1/2} \simeq \frac{1}{\sqrt{3}\pi} \frac{\kappa M^2}{\sigma_0^3}. \quad (15)$$

In the absence of the SUGRA correction, the gauge symmetry breaking scale M is given by Eq. (9). For

$\kappa \gg 10^{-3}$, $x_0 \gg 1$ and $x_0 y_0 f(x_0^2) \rightarrow 1^-$. $\mathcal{P}_{\mathcal{R}}^{1/2}$ in this case turns out to be proportional to $(M/m_P)^2$ [3, 4]. Using the WMAP best fit $\mathcal{P}_{\mathcal{R}}^{1/2} \simeq 4.7 \times 10^{-5}$ [16], M approaches the value $\mathcal{N}^{1/4} \cdot 6 \times 10^{15} \text{ GeV}$. The presence of the SUGRA term leads to larger values of σ_0 and hence larger values of M for $\kappa \gtrsim 0.06/\sqrt{\mathcal{N}}$.

For $\kappa \ll 10^{-3}$, $|S_0| \simeq M$ where S_0 is the value of the field at k_0 , i.e. $z \simeq 1$. (Note that due to the flatness of the potential the last 55 or so e-folds occur with $|S|$ close to M .) From Eqs. (8, 13), as $z \rightarrow 1$

$$\mathcal{P}_{\mathcal{R}}^{1/2} = \frac{2\sqrt{2}\pi}{\sqrt{3}} \frac{\kappa^2 M^4}{\ln(2)\kappa^3 M \mathcal{N} + 8\pi^2 \kappa M^5 + 4\pi^2 a m_{3/2}}. \quad (16)$$

The denominator of Eq. (16) contains the radiative, SUGRA and the A terms respectively. Comparing them, we see that the radiative term can be ignored for $\kappa \lesssim 10^{-4}$. There is also a soft mass term $m_{3/2}^2 |S|^2$ in the potential, corresponding to an additional term $8\pi^2 m_{3/2}^2/\kappa M$ in the denominator. We have omitted this term, since it is insignificant for $\kappa \gtrsim 10^{-5}$.

For a positive A term ($a > 0$), the maximum value of $\mathcal{P}_{\mathcal{R}}^{1/2}$ as a function of M is found to be

$$\mathcal{P}_{\mathcal{R}}^{1/2} \text{ max} = \frac{1}{2^{7/10} 5^{3/2} 3\pi} \left(\frac{\kappa^6}{a m_{3/2}} \right)^{1/5}. \quad (17)$$

Setting $\mathcal{P}_{\mathcal{R}}^{1/2} \simeq 4.7 \times 10^{-5}$, we find a lower bound on κ ($\simeq 10^{-5}$). For larger values of κ , there are two separate solutions of M for a given κ . The solution with larger M is not valid if the symmetry breaking pattern produces cosmic strings. For example, strings are produced when $\Phi, \bar{\Phi}$ break $U(1)_{\bar{R}} \times U(1)_{B-L}$ to $U(1)_Y \times Z_2$ matter parity, but not when $\Phi, \bar{\Phi}$ are $SU(2)_R \times U(1)_{B-L}$ doublets. For $a < 0$, there are again two solutions, but for the solution with a lower value of M , the slope changes sign as the inflaton rolls for $\kappa \lesssim 10^{-4}$ and the inflaton gets trapped in a false vacuum.

Note that the A term depends on $\arg S$, so it should be checked whether $\arg S$ changes significantly during inflation. Numerically, we find that it does not, except for a range of κ around 10^{-4} [2]. For this range, if the initial value of the S field is greater than M by at least a factor of two or so, the A term and the slope become negative even if they were initially positive, before inflation can suitably end. However, larger values of the A term, or the mass term coming from a non-minimal Kähler potential (or from a hidden sector VEV) would drive the value of M in that region up, allowing the slope to stay positive (see [17] for the effect of varying the A term and the mass).

The dependence of M on κ is shown in Fig. 1. Note that with inflation linked to the breaking of $\text{MSSM} \times U(1)_{B-L}$, M corresponds to the $U(1)_{B-L}$ breaking scale, which is not fixed by the evolution of the three SM gauge couplings. The amplitude of the curvature perturbation (or, equivalently, $\delta T/T$) determines this scale

FIG. 1: The value of the symmetry breaking scale M vs. κ , for SUSY hybrid inflation with $\mathcal{N} = 1$ (solid), and for shifted hybrid inflation (dot-dashed for $M_S = m_P$, dotted for $M_S = 5 \times 10^{17}$ GeV). Light grey portions of the curves are for $a < 0$, where only the segments that do not overlap with the solutions for $a > 0$ are shown. The grey segments denote the range of κ for which the change in $\arg S$ is significant.

to be close to the SUSY GUT scale, suggesting that $U(1)_{B-L}$ could be embedded in $SO(10)$ or its subgroups. For example, M can be determined in flipped $SU(5)$ from the renormalization group evolution of the $SU(3)$ and $SU(2)$ gauge couplings. The values are remarkably consistent with the ones fixed from $\delta T/T$ considerations [18].

Here, some remarks concerning the allowed range of κ is in order. As discussed above, a lower bound on κ is obtained from the inflationary dynamics and the amplitude of the curvature perturbation. An upper bound on κ is obtained from the value of the spectral index, which we discuss next. The gravitino constraint provides a more stringent upper bound ($\kappa \lesssim 10^{-2}$), as discussed in the next section. If cosmic strings form (as would be the case for $\mathcal{N} = 1$), the range of κ is also restricted by the limits on the cosmic string contribution to $\mathcal{P}_{\mathcal{R}}^{1/2}$, however most of the range may still be allowed [17].

In the absence of SUGRA corrections, the scalar spectral index n_s for $\kappa \gg 10^{-3}$ is given by [4]

$$n_s \simeq 1 + 2\eta \simeq 1 - \frac{1}{N_0} \simeq 0.98, \quad (18)$$

while it approaches unity for small κ . When the SUGRA correction is taken into account, from Eq. (14),

$$n_s \simeq 1 + 2\eta \simeq 1 + 2 \left(3\sigma^2 - \frac{\kappa^2 \mathcal{N}}{8\pi^2 \sigma^2} \right), \quad (19)$$

and it exceeds unity for $\sigma^2 \gtrsim \kappa \sqrt{\mathcal{N}} / 2\sqrt{3}\pi$. For $x_0 \gg 1$,

$$N_0 = \int_{\sigma_{end}}^{\sigma_0} \frac{V}{V'} d\sigma \approx \frac{\pi}{2\sigma_0^2} \frac{\kappa}{\kappa_c} \tan \left(\frac{\pi}{2} \frac{\kappa}{\kappa_c} \right), \quad (20)$$

where $\kappa_c = \pi^2 / \sqrt{\mathcal{N}} N_0 \simeq 0.16 / \sqrt{\mathcal{N}}$. Using Eq. (20), one finds that the spectral index n_s exceeds unity for $\kappa \simeq 2\pi / \sqrt{3\mathcal{N}} N_0 \simeq 0.06 / \sqrt{\mathcal{N}}$. The dependence of n_s on κ is displayed in Fig. 2. $dn_s/d \ln k$ is small and the tensor to scalar ratio r is negligible, as shown in Fig. 3.

FIG. 2: The spectral index n_s vs. κ , for SUSY hybrid inflation with $\mathcal{N} = 1$ (solid), and for shifted hybrid inflation with $M_S = m_P$ (dot-dashed). The grey segments denote the range of κ for which the change in $\arg S$ is significant.

FIG. 3: $dn_s/d \ln k$ vs. κ (top) and tensor to scalar ratio r vs. κ (bottom), for SUSY hybrid inflation with $\mathcal{N} = 1$ (solid), and for shifted hybrid inflation with $M_S = m_P$ (dot-dashed).

The experimental data disfavor n_s values in excess of unity on smaller scales (say $k \lesssim 0.05 \text{ Mpc}^{-1}$), which leads to $\kappa \lesssim 0.1 / \sqrt{\mathcal{N}}$ for $n_s \leq 1.04$.⁴ Thus, even for the largest allowed κ the vacuum energy density during inflation is considerably smaller than the symmetry breaking scale, and the tensor to scalar ratio $r \lesssim 10^{-4}$.

Note that the initial WMAP analysis suggests a running spectral index, with $|dn_s/d \ln k| \lesssim 10^{-3}$ disfavored at the 2σ level [16]. On the other hand, an analysis including the constraints from the Sloan Digital Sky Survey (SDSS) finds no evidence for running, with $n_s = 0.98 \pm 0.02$ and $dn_s/d \ln k = -0.003 \pm 0.010$ [20]. Clearly, more data is necessary to resolve this important issue. Modifications of the models discussed here, generally involving two stages of inflation, have been proposed in [15, 21] and elsewhere to generate a much more significant variation of n_s with k .

The inflationary scenario based on the superpotential W_1 in Eq. (1) has the characteristic feature that the

⁴ Larger values of κ are allowed in models where dissipative effects are significant. Such effects become important for large values of κ , provided the inflaton also has strong couplings to matter fields [19].

end of inflation essentially coincides with the gauge symmetry breaking. Thus, modifications should be made to W_1 if the breaking of G to H leads to the appearance of topological defects such as monopoles or domain walls. For instance, the breaking of $G_{PS} \equiv SU(4)_c \times SU(2)_L \times SU(2)_R$ [22] to the MSSM by fields belonging to $\Phi(\bar{4}, 1, 2)$, $\bar{\Phi}(4, 1, 2)$ produces magnetic monopoles that carry two quanta of Dirac magnetic charge [23]. As shown in [24], one simple resolution of the topological defects problem is achieved by supplementing W_1 with a non-renormalizable term:

$$W_2 = \kappa S(\bar{\Phi}\Phi - v^2) - \frac{S(\bar{\Phi}\Phi)^2}{M_S^2}, \quad (21)$$

where v is comparable to the SUSY GUT scale $M_{\text{GUT}} \simeq 2 \times 10^{16}$ GeV and M_S is an effective cutoff scale. The dimensionless coefficient of the non-renormalizable term is absorbed in M_S . The presence of the non-renormalizable term enables an inflationary trajectory along which the gauge symmetry is broken. Thus, in this ‘shifted’ hybrid inflation model the topological defects are inflated away.

The inflationary potential is similar to Eq. (13) [24]:

$$V_2 = \kappa^2 m^4 \left[1 + \frac{\kappa^2}{16\pi^2} \left(2 \ln \frac{\kappa^2 |S|^2}{\Lambda^2} + (z+1)^2 \ln(1+z^{-1}) + (z-1)^2 \ln(1-z^{-1}) \right) + \frac{|S|^4}{2} \right] + a m_{3/2} \kappa v^2 |S|. \quad (22)$$

Here $m^2 = v^2(1/4\xi - 1)$ where $\xi = v^2/\kappa M_S^2$, $z \equiv x^2 \equiv \sigma^2/m^2$, and $2 - A$ is replaced by $2 - A + A/2\xi$ in the expression for a .⁵ Just like in the previous section, for $\kappa \lesssim 0.01$ the SUGRA correction is negligible, and one obtains Eq. (9) with $\mathcal{N}$ replaced by 2, Eq. (5) with $\mathcal{N}$ replaced by 4, and M replaced by m in both equations. The slow roll parameters (and therefore n_s , $dn_s/d \ln k$, and r) are identical to the SUSY hybrid inflation model with $\mathcal{N} = 2$ for $z \gg 1$ (Fig. 2).

The VEV $M = |\langle \nu_H^c \rangle| = |\langle \bar{\nu}_H^c \rangle|$ at the SUSY minimum is given by [24]

$$\left(\frac{M}{v} \right)^2 = \frac{1}{2\xi} \left(1 - \sqrt{1 - 4\xi} \right), \quad (23)$$

and is $\sim 10^{16} - 10^{17}$ GeV depending on κ and M_S . The system follows the inflationary trajectory for $1/7.2 < \xi < 1/4$ [24], which is satisfied for $\kappa \gtrsim 10^{-5}$ if the effective cutoff scale $M_S = m_P$. For lower values of M_S , the inflationary trajectory is followed only for higher values of κ , and M is lower for a given κ (Fig. 1).

A variation on these inflationary scenarios is obtained by imposing a Z_2 symmetry on the superpotential, so

that only even powers of the combination $\Phi\bar{\Phi}$ are allowed [25]:

$$W_3 = S \left(-v^2 + \frac{(\Phi\bar{\Phi})^2}{M_S^2} \right), \quad (24)$$

where the dimensionless parameter κ is absorbed in v . The resulting scalar potential possesses two (symmetric) valleys of local minima which are suitable for inflation and along which the GUT symmetry is broken. The inclination of these valleys is already non-zero at the classical level and the end of inflation is smooth, in contrast to inflation based on the superpotential W_1 (Eq. (1)). An important consequence is that, as in the case of shifted hybrid inflation, potential problems associated with topological defects are avoided.

The common VEV at the SUSY minimum $M = |\langle \nu_H^c \rangle| = |\langle \bar{\nu}_H^c \rangle| = (v M_S)^{1/2}$. For $\sigma^2 \gg M^2$, the inflationary potential is given by

$$V_3 \approx v^4 \left[1 - \frac{2}{27} \frac{M^4}{\sigma^4} + \frac{\sigma^4}{8} \right], \quad (25)$$

where the last term arises from the canonical SUGRA correction. The soft terms in this case do not have a significant effect on the inflationary dynamics. If we set M equal to the SUSY GUT scale M_{GUT} , we get $v \simeq 1.4 \times 10^{15}$ GeV and $M_S \simeq 2.8 \times 10^{17}$ GeV. (Note that, if we express Eq. (24) in terms of the coupling parameter κ , this value corresponds to $\kappa \sim O(v^2/M_{\text{GUT}}^2) \sim 10^{-2}$.) The value of the field σ is 1.1×10^{17} GeV at the end of inflation (corresponding to $\eta = -1$) and is $\sigma_0 \simeq 2.4 \times 10^{17}$ GeV at k_0 . In the absence of the SUGRA correction (which is small for $M \lesssim 10^{16}$ GeV), $\sigma \propto M^{2/3} m_P^{1/3}$, $(\delta T/T)_0 \propto M^{10/3}/(M_S^2 m_P^{4/3})$ and the spectral index is given by [25]

$$n_s \simeq 1 - \frac{5}{3N_0} \simeq 0.97, \quad (26)$$

a value which coincides with the prediction of some D-brane inflation models [26]. This may not be surprising since, in the absence of SUGRA correction, the potential V_3 (Eq. (25)) has a form familiar from D-brane inflation. The SUGRA correction raises n_s from 0.97 to 1.0 for $M \sim 10^{16}$ GeV, and above unity for $M \gtrsim 1.5 \times 10^{16}$ GeV (Fig. 4).

III. LEPTOGENESIS IN SUPERSYMMETRIC HYBRID INFLATION MODELS

An important constraint on SUSY hybrid inflation models arises from considering the reheat temperature T_r after inflation, taking into account the gravitino problem which requires that $T_r \lesssim 10^6 - 10^{11}$ GeV [27]. This constraint on T_r depends on the SUSY breaking mechanism and the gravitino mass $m_{3/2}$. For gravity mediated SUSY breaking models with unstable gravitinos of

⁵ Note that the potential also contains a mass term even for minimal Kähler potential, due to the nonvanishing VEVs of Φ , $\bar{\Phi}$. This term, however, does not have a significant effect for the range of parameters where $v \lesssim 10^{17}$ GeV.

FIG. 4: The spectral index n_s as a function of the gauge symmetry breaking scale M for smooth hybrid inflation (dashed line—without SUGRA correction, solid line—with SUGRA correction).

mass $m_{3/2} \simeq 0.1\text{--}1$ TeV, $T_r \lesssim 10^6\text{--}10^9$ GeV [28], while $T_r \lesssim 10^{10}$ GeV for stable gravitinos [29]. In gauge mediated models the reheat temperature is generally more severely constrained, although $T_r \sim 10^9\text{--}10^{10}$ GeV is possible for $m_{3/2} \simeq 5\text{--}100$ GeV [30]. Finally, the anomaly mediated symmetry breaking (AMSB) scenario may allow gravitino masses much heavier than a TeV, thus accommodating a reheat temperature as high as 10^{11} GeV [31].

After the end of inflation in the models discussed in section II, the fields fall toward the SUSY vacuum and perform damped oscillations about it. The vevs of $\bar{\Phi}$, Φ along with their right handed neutrino components $\bar{\nu}_H^c$, ν_H^c break the gauge symmetry. The oscillating system, which we collectively denote as χ , consists of the two complex scalar fields $(\delta\bar{\nu}_H^c + \delta\nu_H^c)/\sqrt{2}$ (where $\delta\bar{\nu}_H^c$, $\delta\nu_H^c$ are the deviations of $\bar{\nu}_H^c$, ν_H^c from M) and S , with equal mass m_χ .

We assume here that the inflaton χ decays predominantly into right handed neutrino superfields N_i , via the superpotential coupling $(1/m_P)\gamma_{ij}\bar{\phi}\bar{\phi}N_iN_j$ or $\gamma_{ij}\bar{\phi}N_iN_j$, where i, j are family indices (see below for a different scenario connected to the resolution of the MSSM μ problem). Their subsequent out of equilibrium decay to lepton and Higgs superfields generates lepton asymmetry, which is then partially converted into the observed baryon asymmetry by sphaleron effects [32].

The right handed neutrinos, as shown below, can be heavy compared to the reheat temperature T_r . Note that unlike thermal leptogenesis, there is then no washout factor since lepton number violating 2-body scatterings mediated by right handed neutrinos are out of equilibrium as long as the lightest right handed neutrino mass $M_1 \gg T_r$ [33]. More precisely, the washout factor is proportional to e^{-z} where $z = M_1/T_r$ [34], and can be neglected for $z \gtrsim 10$. Without this assumption, the constraints to generate sufficient lepton asymmetry would be more stringent.

GUTs typically relate the Dirac neutrino masses to that of the quarks or charged leptons. It is therefore reasonable to assume the Dirac masses are hierarchical.

The low-energy neutrino data indicates that the right handed neutrinos in this case will also be hierarchical in general. As discussed in Ref. [35], setting the Dirac masses strictly equal to the up-type quark masses and fitting to the neutrino oscillation parameters generally yields strongly hierarchical right handed neutrino masses ($M_1 \ll M_2 \ll M_3$), with $M_1 \sim 10^5$ GeV. The lepton asymmetry in this case is too small by several orders of magnitude. However, it is plausible that there are large radiative corrections to the first two family Dirac masses, so that M_1 remains heavy compared to T_r .

A reasonable mass pattern is therefore $M_1 < M_2 \ll M_3$, which can result from either the dimensionless couplings γ_{ij} or additional symmetries (see e.g. [21]). The dominant contribution to the lepton asymmetry is still from the decays with N_3 in the loop, as long as the first two family right handed neutrinos are not quasi degenerate. Under these assumptions, the lepton asymmetry is given by [36]

$$\frac{n_L}{s} \lesssim 3 \times 10^{-10} \frac{T_r}{m_\chi} \left(\frac{M_i}{10^6 \text{ GeV}} \right) \left(\frac{m_{\nu 3}}{0.05 \text{ eV}} \right), \quad (27)$$

where M_i denotes the mass of the heaviest right handed neutrino the inflaton can decay into. The decay rate $\Gamma_\chi = (1/8\pi)(M_i^2/M^2)m_\chi$ [9], and the reheat temperature T_r is given by

$$T_r = \left(\frac{45}{2\pi^2 g_*} \right)^{1/4} (\Gamma_\chi m_P)^{1/2} \simeq 0.063 \frac{(m_P m_\chi)^{1/2}}{M} M_i. \quad (28)$$

From the experimental value of the baryon to photon ratio $\eta_B \simeq 6.1 \times 10^{-10}$ [16], the required lepton asymmetry is found to be $n_L/s \simeq 2.5 \times 10^{-10}$ [37]. Using this value, along with Eqs. (27, 28), we can express T_r in terms of the symmetry breaking scale M and the inflaton mass m_χ :

$$T_r \gtrsim \left(\frac{10^{16} \text{ GeV}}{M} \right)^{1/2} \left(\frac{m_\chi}{10^{11} \text{ GeV}} \right)^{3/4} \times \left(\frac{0.05 \text{ eV}}{m_{\nu 3}} \right)^{1/2} 1.6 \times 10^7 \text{ GeV}. \quad (29)$$

Here m_χ is given by $\sqrt{2}\kappa M$, $\sqrt{2}\kappa M\sqrt{1-4\xi}$ and $2\sqrt{2}v^2/M$ respectively for hybrid, shifted hybrid and smooth hybrid inflation. The value of m_χ is shown in Figs. 5 and 6. We show the lower bound on T_r calculated using this equation (taking $m_{\nu 3} = 0.05$ eV) in Figs. 7, 8.

Eq. (28) also yields the result that the heaviest right handed neutrino the inflaton can decay into is about 400 (6) times heavier than T_r , for hybrid inflation with $\kappa = 10^{-5}$ (10^{-2}). For shifted hybrid inflation, this ratio does not depend on κ as strongly and is $\sim 10^2$ [38]. This is consistent with ignoring washout effects as long as the lightest right handed neutrino mass M_1 is also $\gg T_r$.

Both the gravitino constraint and the constraint $M_1 \gg T_r$ favor smaller values of κ for hybrid inflation, with

FIG. 5: The inflaton mass m_χ vs. κ , for SUSY hybrid inflation with $\mathcal{N} = 1$ (solid), and for shifted hybrid inflation (dot-dashed for $M_S = m_P$, dotted for $M_S = 5 \times 10^{17}$ GeV). The grey segments denote the range of κ for which the change in $\arg S$ is significant.

FIG. 6: The inflaton mass m_χ vs. the symmetry breaking scale M for smooth hybrid inflation.

$T_r \gtrsim 2 \times 10^7$ GeV for $\kappa \sim 10^{-5}$. Similarly, the gravitino constraint favors κ values as small as the inflationary trajectory allows for shifted hybrid inflation, and $T_r \gtrsim 5 \times 10^7$ GeV for $M_S = m_P$. Smooth hybrid inflation is relatively disfavored since $T_r \gtrsim 4 \times 10^9$ and $M_2/T_r \simeq 4$ (12) for $M = 5 \times 10^{15}$ GeV (2×10^{16} GeV).⁶

So far we have not addressed the μ problem and the relationship to T_r in the present context. The MSSM μ problem can naturally be resolved in SUSY hybrid inflation models in the presence of the term $\lambda S h^2$ in the superpotential, where h contains the two Higgs doublets [39]. (The ‘bare’ term h^2 is not allowed by the $U(1)$ R-symmetry.) After inflation the VEV of S generates a μ term with $\mu = \lambda \langle S \rangle = -m_{3/2} \lambda / \kappa$, where $\lambda > \kappa$ is required for the proper vacuum. The inflaton in this case predominantly decays into higgses (and higgsinos) with $\Gamma_h = (1/16\pi) \lambda^2 m_\chi$. As a consequence the presence of this term significantly increases the reheat temperature T_r . Following [40], we calculate T_r for the best case scenario $\lambda = \kappa$. We find a lower bound on T_r of 4×10^8

FIG. 7: The lower bound on the reheat temperature T_r vs. κ , for SUSY hybrid inflation with $\mathcal{N} = 1$ (solid) and for shifted hybrid inflation (dot-dashed for $M_S = m_P$, dotted for $M_S = 5 \times 10^{17}$ GeV). The segments in the top left part of the figure correspond to the bounds in the presence of a $\lambda S h^2$ coupling. The grey segments denote the range of κ for which the change in $\arg S$ is significant.

FIG. 8: The lower bound on the reheat temperature T_r vs. the symmetry breaking scale M for smooth hybrid inflation.

GeV in hybrid inflation, see Fig. 7. $T_r \gtrsim 4 \times 10^9$ GeV for shifted hybrid inflation with $M_S = m_P$ ⁷, and $T_r \gtrsim 10^{12}$ GeV for smooth hybrid inflation. An alternative resolution of the μ problem in SUSY hybrid inflation involves a Peccei-Quinn (PQ) symmetry $U(1)_{PQ}$ [24, 41].

The lower bounds on T_r are summarized in Table 1. Even for hybrid and shifted models, there is some tension between the gravitino constraint and the reheat temperature required to generate sufficient lepton asymmetry, particularly for gravity mediated SUSY breaking models, and if hadronic decays of gravitinos are not suppressed. However, we should note that having quasi degenerate neutrinos would increase the lepton asymmetry per neutrino decay ϵ [42] and thus allow lower values of T_r corresponding to lighter right handed neutrinos. Provided that the neutrino mass splittings are comparable to their decay widths, ϵ can be as large as $1/2$ [43]. The lepton asymmetry in this case is of order T_r/m_χ where

⁶ A new inflation model related to smooth hybrid inflation is discussed in [11, 21], where the energy scale of inflation is lower and consequently lower reheat temperatures are allowed.

⁷ We take $\lambda/\kappa = 2/(1/4\xi - 1)$ for shifted hybrid inflation. Some scalars belonging to the inflaton sector acquire negative (mass)² if λ is smaller. $\kappa \sim 10^{-4}$ corresponds to $\lambda/\kappa \simeq 3$.

TABLE I: Lower bounds on the reheat temperature (GeV)

	without λSh^2	with λSh^2
SUSY hybrid inflation	2×10^7	4×10^8
Shifted hybrid inflation	5×10^7	4×10^9
Smooth hybrid inflation	4×10^9	$\gtrsim 10^{12}$

$m_\chi \sim 10^{11}$ GeV for $\kappa \sim 10^{-5}$, and sufficient lepton asymmetry can be generated with T_r close to the electroweak scale.

IV. SUMMARY

- MSSM $\times Z_2$ (matter parity), when extended to MSSM $\times U(1)_{B-L} \times U(1)_R$ helps us to implement inflation and leptogenesis; natural extensions include $SO(10)$ and its various subgroups;

- The $U(1)_{B-L}$ breaking scale is constrained from $\delta T/T$ to be of order the SUSY GUT scale;
- The spectral index is predicted to be 0.99 ± 0.01 , with a negligible tensor to scalar ratio and $dn_s/d\ln k \lesssim 10^{-3}$. For smooth hybrid inflation $n_s \geq 0.97$;
- $U(1)_R$ contains Z_2 matter parity, eliminates Planck suppressed dimension five proton decay, and may play an essential role in resolving the MSSM μ problem.
